

CSCI262 – System Security

Client Puzzle

14 October 2022

- 1) One of the client puzzles we considered contained the statement $h(C, Ns, Nc, Y) = 000 \dots 000X$.
 - a. Describe each of the components in the expression above.
 - b. How much work is required to "solve" the puzzle, in the context of this statement?
 - c. What is the purpose of such a puzzle?
 - d. Describe how we could modify this to generate subpuzzles.
 - e. What advantage do we obtain by using many subpuzzles rather than just one single large puzzle?

$$h(C, Ns, Nc, Y) = 000 \dots 000X.$$

a) Describe each of the components in the expression above.

$$h(C, Ns, Nc, Y) = 000 \dots 000X.$$

- a) Describe each of the components in the expression above.
 - h: a cryptographic hash function (e.g., MD5 or SHA)
 - *C*: the client identity
 - N_s : the server's nonce
 - N_c : the client's nonce
 - *Y*: the solution of the puzzle
 - $000 \dots 000$: the k first bits of the hash value; must be zero. The reasonable values of k lie between 0 and 64.
 - X: the rest of the hash value; may be anything

b) How much work is required to "solve" the puzzle, in the context of this statement?

b) How much work is required to "solve" the puzzle, in the context of this statement?

The cost of solving the puzzle depends exponentially on the required number of k of zero bits in the beginning of the hash. If k=0, no work is required. If k=64, then in the worst case, it would be 2^k . In such a puzzle, the reasonable values of k lie between 0 and 64.

c) What is the purpose of such a puzzle?

c) What is the purpose of such a puzzle?

The purpose of such a puzzle is to ensure that the client should always commit its resources to the authentication protocol first and the server should be able to verify the client commitment before allocating its own resources.

d) Describe how we could modify this to generate sub-puzzles.

d) Describe how we could modify this to generate sub-puzzles.

The modification can be done as follow:

The Server:

- Server determines k.
- Server generates two nonce N_S and $N_{S'}$, and a timestamp T_S .
- Server sends the two puzzles with sequence number $(1, N_s)$ and $(2, N_{s'})$, the timestamp T_s and the puzzle difficulty level k to client.

Client

Server

The Client:

- Client receive the puzzles and commits its resources into solving the puzzle.
- Client verifies the timestamp T_s .
- Client generates two nonce N_c and $N_{c'}$
- Client finds Y such that $h(1, C, N_s, N_c, Y) = 000 \dots 000 X$, where $000 \dots 000$ denotes $k \ 0's$, and X can be any value.
- Client finds the second solution Y' such that $h(2,C,N_{s'},N_{c'},Y')=000\dots000X$, where $000\dots000$ denotes k 0's, and X can be any value.

• Client sends the solutions (solved puzzles) $(S, 1, C, N_s, N_c, Y)$ and $(S, 2, C, N_{s'}, N_{c'}, Y')$ to server.

Client $(S, 1, C, N_s, N_c, Y), (S, 2, C, N_{s'}, N_{c'}, Y')$ Server

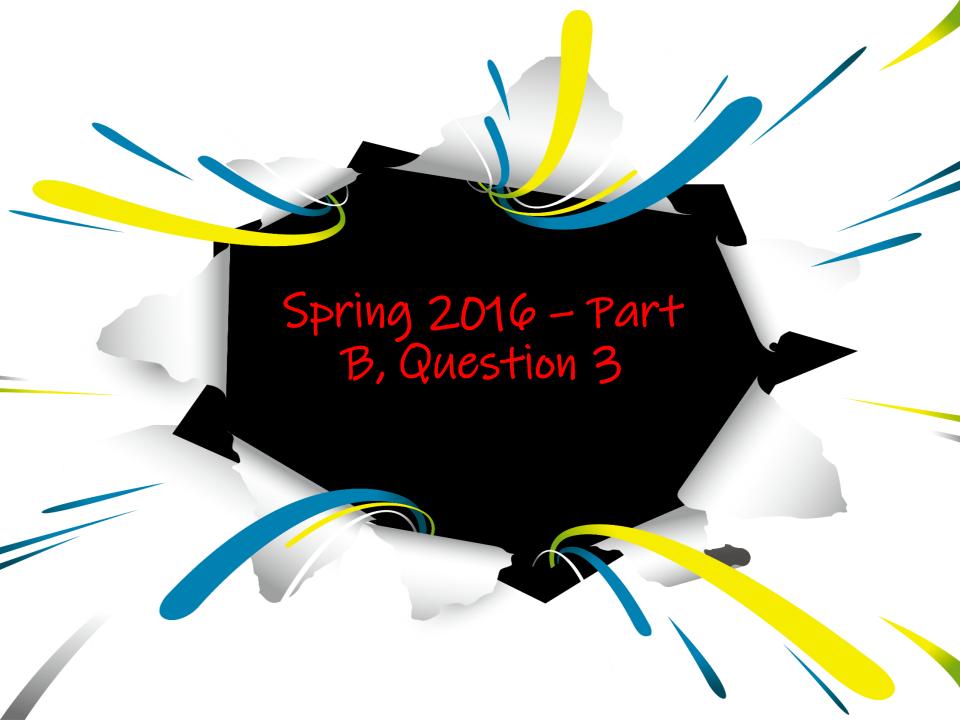

The Server:

- verifies that N_s and $N_{s'}$ are recent.
- checks that C, N_s , $N_{s'}$, N_c , and $N_{c'}$ have not been used before.
- checks if there are k 0's in each solution, that is, the server checks if $h(1,C,N_s,N_c,Y)=000\dots000X$ and $h(2,C,N_{s'},N_{c'},Y')=000\dots000X$ are correct.
- If they do, the server commits the resources, stores $(C, N_S, N_{S'}, N_C, N_{C'})$ and sends $(S, C, N_C, N_{C'})$ to the client.
- The operation can now continue.

e) What advantage do we obtain by using many subpuzzles rather than just one single large puzzle?

e) What advantage do we obtain by using many subpuzzles rather than just one single large puzzle?

If we use a single big puzzle instead of sub puzzles, then the difficulty level is hard to adjust. This is because one bit of change in *k* could require a much longer time to solve the puzzle. Using sub puzzles we can fine tune the difficulty level.

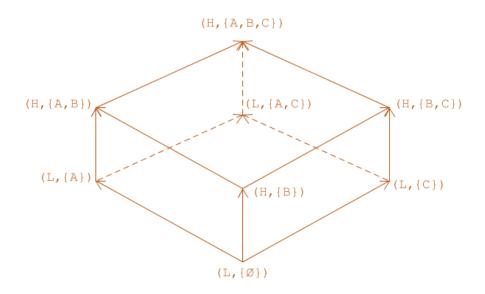

CSCI262-System Security

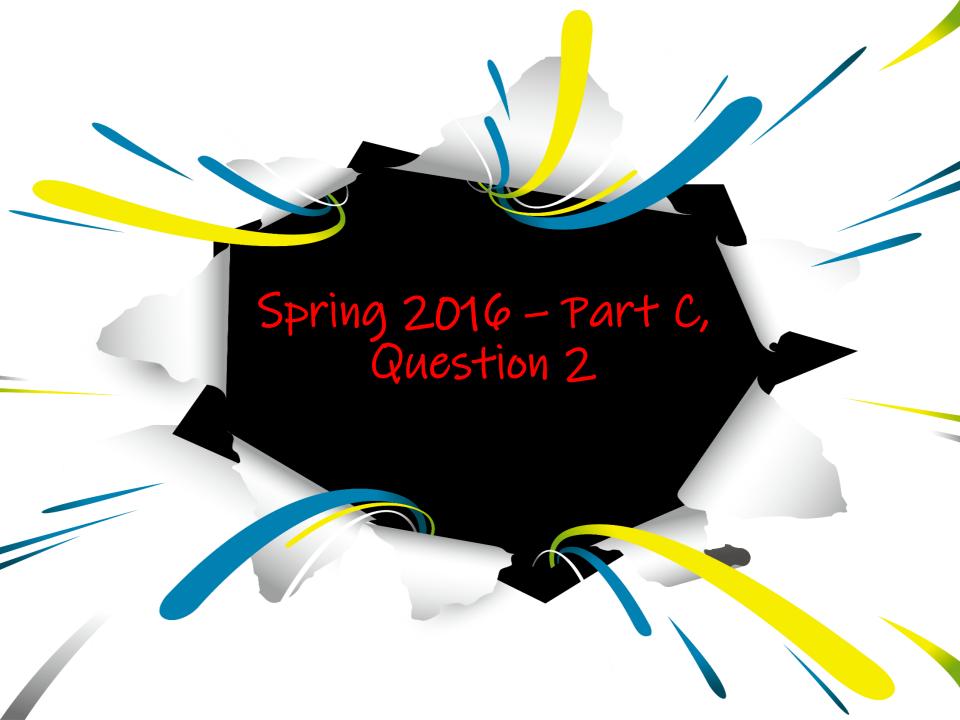

• A company has three departments A, B and C, and has determined that it is appropriate to have two levels of sensitivity, in increasing order: L and H. Draw a BLP lattice system to represent this scenario.

CSCI262 – System Security - Spring Session 2016, Part B, Question 3

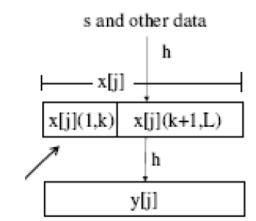

Spring 2016, Part C - Question 2

- 2) Consider the diagram to the right and answer the following questions:
 - a. What is the context of this diagram?
 - b. What is sent to the client and how is this generated?
 - c. What should the client respond with?
 - d. What is the role of k?
 - e. How much work would we expected the client to do?
 - f. Is the answer from the client unique? Justify your answer.

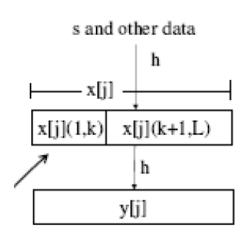

a. What is the context of this diagram?

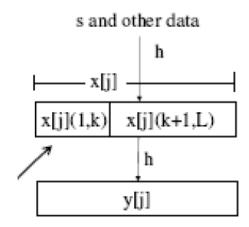

a. What is the context of this diagram?

The diagram refers to the construction of client puzzles.

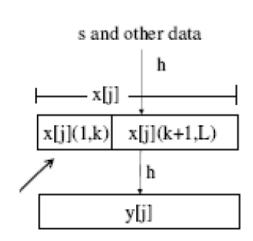

b. What is sent to the client and how is this generated?

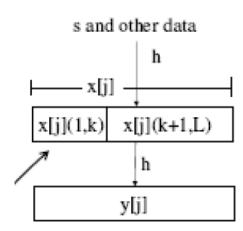

b. What is sent to the client and how is this generated?

X[j](k+1,L) is sent to the client. This is generated by taking a subpuzzle and taking k bit as the solution of the puzzle

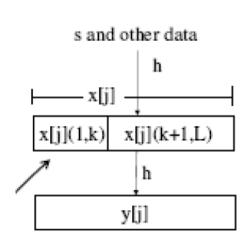

c. What should the client respond with?

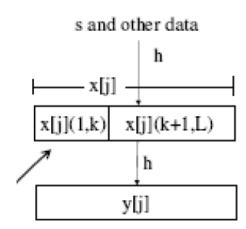

c. What should the client respond with?

The client should respond with x[j](1,k) to be joined with x[j](k+1,L) to get y[j].

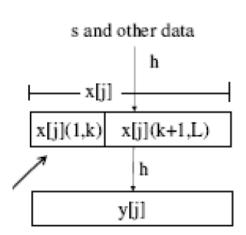

d. What is the role of k?

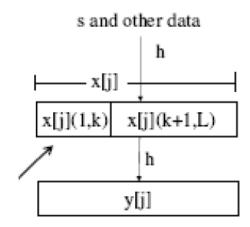

d. What is the role of k?

k is the number of bits that are missing from the puzzle. It determines the complexity (efforts) that a client needs to put in to solve the puzzle.

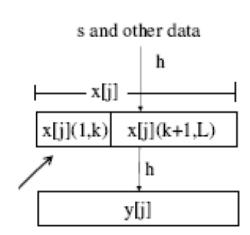

e. How much work would we expected the client to do?

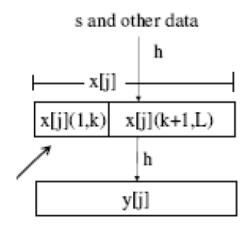

e. How much work would we expected the client to do?

The client is expected to do minimal work so that the authentication can be fast.

f. Is this process stateless? Explain your answer.

f. Is this process stateless? Explain your answer.

Yes, the puzzle stores no information. The solution itself contains all the information the server needs other than their own server secret.
